Improving astrophysical γ-ray modeling with Gaussian processes and variational inference

Siddharth Mishra-Sharma and Kyle Cranmer, New York University

NYU | Center for Cosmology and Particle Physics

Motivation

- Signals of dark matter (DM) may be hiding in γ-ray observations of the Galactic Center
- Galactic backgrounds of astrophysical origin make up a large fraction ($\gtrsim 80\%$) of the data in this region
- The poorly-understood spatial morphology of these backgrounds makes it difficult to characterize DM signals [1-2]
- Motivates analysis techniques that can account for uncertainty in knowledge of Galactic background contribution (e.g., Refs. [3,5])

Dark matter signal model

Two different Galactic background models
Model 1 Model 2
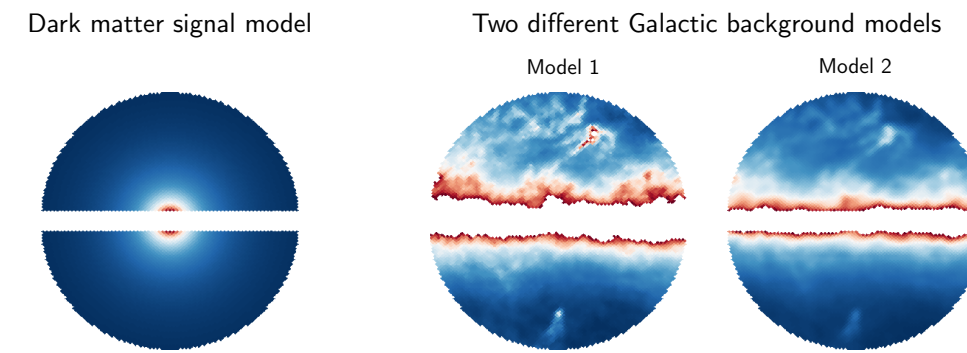

Summary

- Traditional γ-ray analyses model data as a sum of rigid spatial templates, each corresponding to a specific astrophysical component [4]
- We modulate the poorly-understood Galactic background templates by a Gaussian process (GP) in order to give them more freedom and account for uncertainty in their spatial variation
- The GP is included as part of a larger probabilistic model that includes parameters describing other modeled components, including a dark matter signal. Variational inference is used for tractable analysis.
Traditional template fitting

- Spatially-binned (pixelized) data d^p is modeled as a Poisson realization of sum of templates T_i^p ← Pixel index ← Template index
- Spatial profile of each template is rigidly fixed
- Normalizations A_i of templates are floated as free parameters of the model
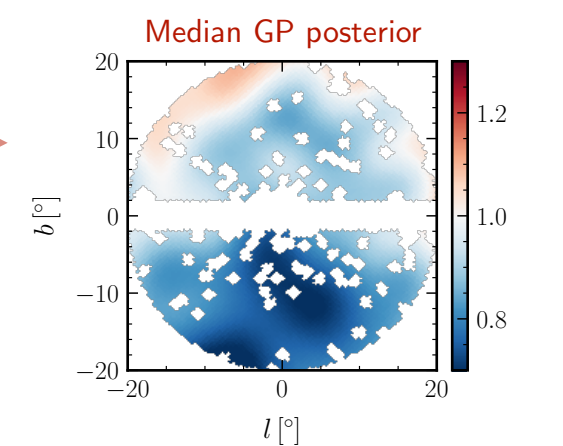

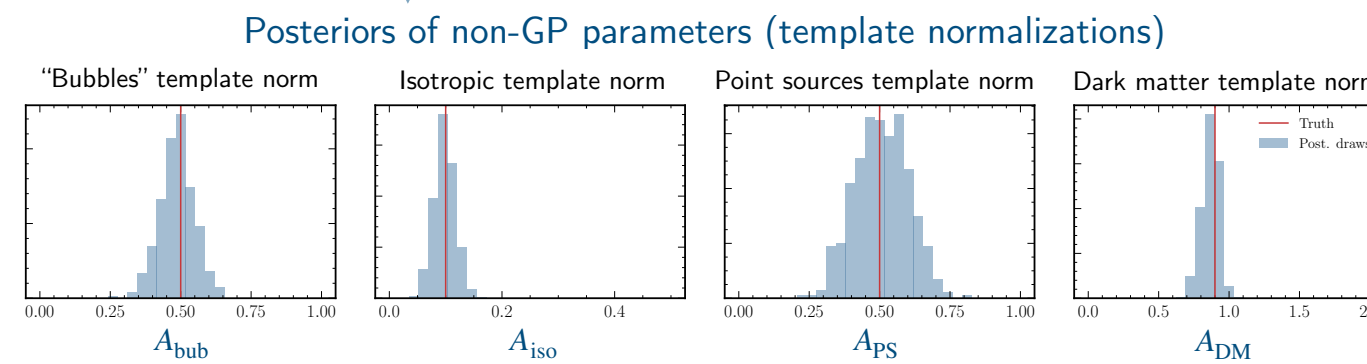

$$d^p \sim \text{Pois}\left(\sum_i A_i T_i^p\right)$$
Augmenting Galactic background (poorly-understood) template with a GP

- Modulate Galactic background template with GP
- Exponential link function to ensure positivity

Full-sky γ-ray data from *Fermi* satellite

Galactic Center region (4234 pixels)
d^p

$= \text{Pois}\Big(A_{\text{bub}} \times$ "Bubbles" template T_{bub} $+ A_{\text{iso}} \times$ Isotropic template T_{iso} $+ A_{\text{PS}} \times$ Point sources template T_{PS} $+ A_{\text{DM}} \times$ Dark matter template T_{DM} $+ \exp(\text{GP}) \times$ $\Big)$

Proof-of-principle analysis on simulated data

- Create simulated data using one Galactic background model (Model 1), analyze using other model (Model 2) (templates from Refs. [5-6])
- GP used for variational posterior defined using GPyTorch [7] and Pyro [8]
- Variational distributions of non-GP parameters (template normalizations) $q(A_i|\text{GP})$ defined using inverse autoregressive flows conditioned on GP summary statistics in order to capture correlations between GP and non-GP parameters

Posteriors of non-GP parameters (template normalizations)

"Bubbles" template norm | Isotropic template norm | Point sources template norm | Dark matter template norm
A_{bub} | A_{iso} | A_{PS} | A_{DM}
